But, let's see, what happens if we don't update immediately the parent pointers in the nodes of the tree set as child? Simply, next time we run `findPartition` on one of the elements in that tree, call it x, we need to walk the tree from x up to its old root xR, and then from xR to the new root R.

Keep in mind that the pointers for the elements in the old tree could have been in sync before the merge (and then we would just need two hops to get to the new root - see figure 5.112), or they could have never been updated.
