

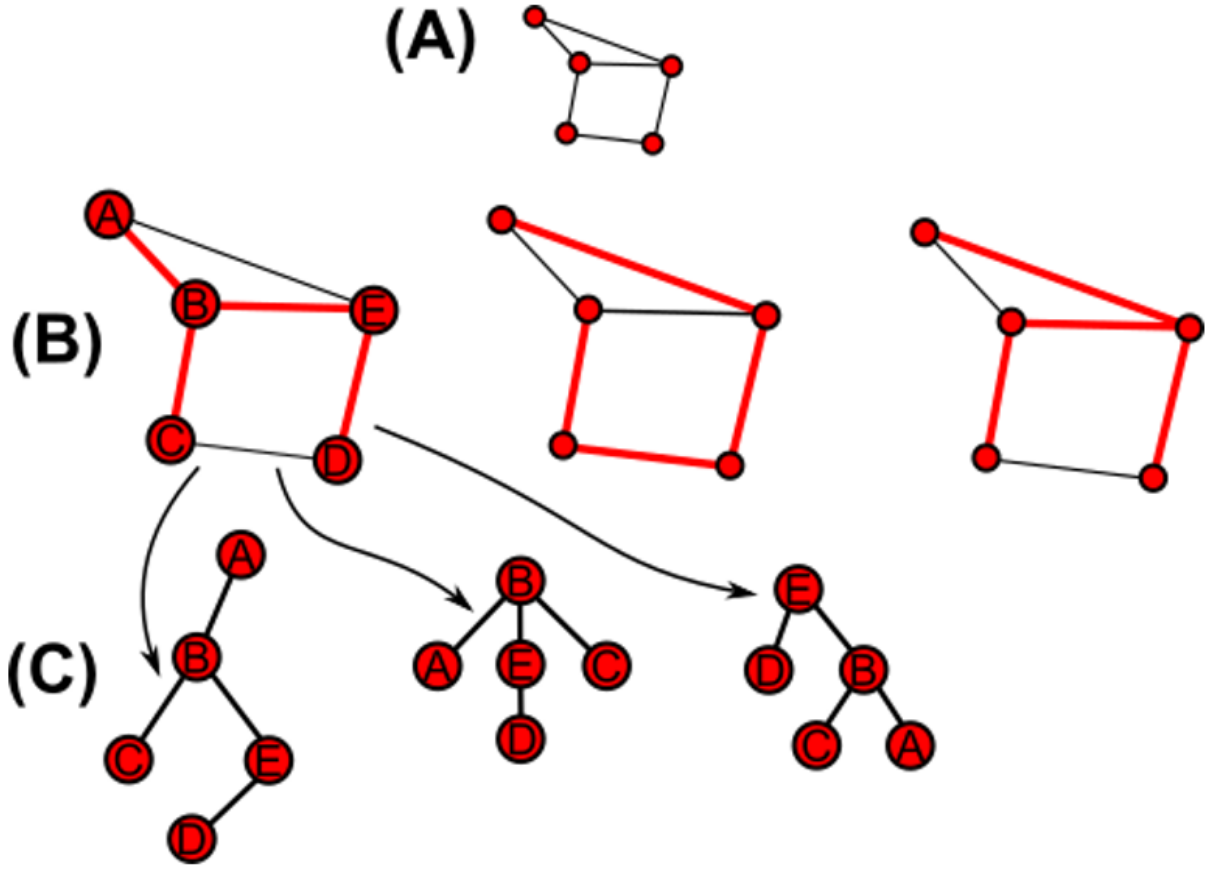

Figure 5.12 An example of a graph with several spanning trees.
(A) An undirected, connected graph, containing cycles.
(B) Since the graph has cycles, there are several spanning trees covering all nodes: a few examples are shown, each of them selecting only the smallest set of edges (the thick ones) that “span” all vertices.
(C) For each set of edges, several trees can be obtained, depending on the root of the tree and the order of the children. (only a few examples are shown: notice, though, how they are not limited to binary trees…)
