```
class RTNode
  #type boolean
  keyNode

  #type HashMap<Char, RTEdge>
  children

  function RTNode(storesKey)
    children ← new HashMap()
    this.keyNode ← storesKey

class RadixTrie
  #type RTNode
  root

  function RadixTrie()
    root ← new RTNode(false)
```

Listing 6.12 shows the pseudocode for the `RadixTrie` and `RTNode` classes, used to model this new data structure. We also added a class to model edges, to make code cleaner. I wonder if you have you noticed a tiny, but meaningful, detail: we don't need to define a fixed alphabet beforehand, like for tries!

You can also take a look at a full implementation on the book's repo on GitHub.

6.3.2 Search

The search method, shown in listing 6.13, is almost identical to the trie's counterpart; the only difference is the way we get the next edge to traverse: since we are going to reuse
