pass-through node.
(4) Compress the path by removing the pass-through node and merging edges.

Besides that, we might have to perform the usual pruning, when deleting a key in a leaf: the difference with tries, in this case, is that we will only have to remove a single edge in radix trees.

Listing 6.16 method remove for Radix Tries

```
function delete(node,
s)                                                    #1
  if s == “” then
                                                      #2
    node.keyNode ←
false                                                    #3
    return (true, node.children ==
0)                                          #4
  else
    (edge, commonPrefix, sSuffix, edgeSuffix) ←
matchEdge(node, s)            #5
    if edge != null and edgeSuffix == “”
then                                    #6
      dest ←
edge.destination
  #7
      (deleted, shouldPrune) ← delete(dest,
sSuffix)                              #8
      if deleted then
        if shouldPrune
then                                                  #9
          node.children[s[0]] ← null
        elsif isPassThrough(dest, node)
then                                     #10
          nextEdge ←
getPassThroughEdge(dest)                                  #11
```
