only one outgoing edge, and moreover even its parent only has one outgoing edge (hence we need to pass the parent too). Implementation is left as an exercise.

- Since pass-through nodes only have 1 outgoing edge, their children field will only have exactly one entry; `getPassThroughEdge` is a wrapper for retrieving this entry.

## 6.3.5 Longest Common Prefix

Porting this method from the trie's version is straightforward: it's just a matter of slightly modifying the search algorithm to keep into account the different way we do edge matching. Listing 6.17 describes the pseudocode for the radix trie's version.

**Listing 6.17 method longestPrefix for Radix Trie**

```
function longestPrefix(node, s,
prefix)                                          #1
  if s == "" then
                                                      #2
    if node.keyNode
then                                                        #3
      return prefix
    else
      return
null
  #4
  (edge, commonPrefix, sSuffix, edgeSuffix) ← matchEdge(node,
s)              #5
  result ←
null
    #6
```
