Listing 6.18 illustrates this new method, called `searchNodeWithPrefix`, to distinguish it from exact match search; the API method `keysStartingWith` and the utility method `allKeysInBranch` are, instead, basically identical to the equivalent method in tries and so we leave its pseudocode as a useful exercise for the reader.

Listing 6.18 method searchNodeForPrefix for Radix Trie

```
function searchNodeWithPrefix(node,
s)                                          #1
  if s == “” then
                                                        #2
    return node
  (edge, commonPrefix, sSuffix, edgeSuffix) ← matchEdge(node,
s)              #3
  if edge == null
then                                                                #4
    return null
  elsif edgeSuffix == “”  then
                                      #5
    return searchNodeWithPrefix (edge.destination,
sSuffix)
  elsif sSuffix == null
then                                                    #6
    return edge.destination
  else
    return
null
    #7
```

#1 Method `longestPrefix` takes a trie node, the string key `s` to be searched, and a string with the path from root to
