	highest priority currently stored in the queue
Data model	An array whose elements are the items stored in the Heap
Invariants	Every element has two “children”. For the element at position *i*, it’s children are located at indices 2*i+1 and 2*(i+1). Every element has higher priority than its children.

2.5.4 Priority, min-heap and max-heap

When we stated the three heap’s properties, we used the wording “highest priority”: in a heap, we can always say that the highest priority element will be at the top, without raising any ambiguity.

Then when it comes to practice, we will have to define what priority means, but if we implement a general-purpose heap, we can safely parameterize it with a custom priority function, taking an element and returning its priority, and as long as our implementation abides by the 3 laws as stated in section 2.5.3, we will be sure our heap works as expected.

Sometimes, however, it’s better to have specialized implementations that leverage the domain knowledge and avoid the overhead of a custom priority function. For instance, if we store tasks in a heap, we can use tuples `(priority, task)` as elements, and rely on the natural ordering of tuples[9].
