[16] JPG algorithm transforms the image from pixel space to frequency space.

[17] Though this is unlikely the case if you are trying to train a robust model, bear with me just for the sake of illustrating this

[18] Quantum computers could come to the rescue, though, in these situations: check out Learn Quantum Computing with Python and Q#.

[19] Of course, especially if we have a lot of data, we have no guarantee that these two fields alone will be unique, as two people can share the same birthdate and name. Let's assume, just to keep our example simple, this is the case.

[20] Select * is usually frowned upon, and for good reasons. We'll use it here to keep code simple, but you should only select the fields you actually need to use.

[21] In our example implementation in listing 9.12, we passed a tuple of min-max objects

[22] As an alternative to implementing explicitly the partial match query, we can use the pointsInRectangle method, by carefully choosing the ranges for the fields that have no restrictions.
