ones to the source, to the ones furthest away. The container used to keep track of the vertices in the frontier could be a priority queue, but it would be overkill: since the metric we use to compute the distance of each vertex from the source is just the number of edges traveled, turns out that the algorithm naturally discover vertices in the same order in which they need to be processed. Furthermore, each vertex' distance can be computed at the time of discovery (the first time each vertex is found while visiting another vertex adjacency list).
