Similarly to BFS, there is no guarantee that a single run of a DFS traversal will visit all vertices in the graph: this is shown in figure 14.12, where instead of starting the traversal from v_1, we choose to start from v_4: since the graph has 2 strongly connected components, and the first one can't be reached from v_4, this unavoidably means that vertices v_1 to v_3 can't be visited in this traversal.
