the source and the destination, and it's also the path of minimum *Manhattan Distance*[7].

And yet, by just removing the edge between vertices v_9 and v_E, the result would have to change completely: try it out, as an exercise, to work out the solution for this modified case (manually or by writing your own version of BFS and running it).

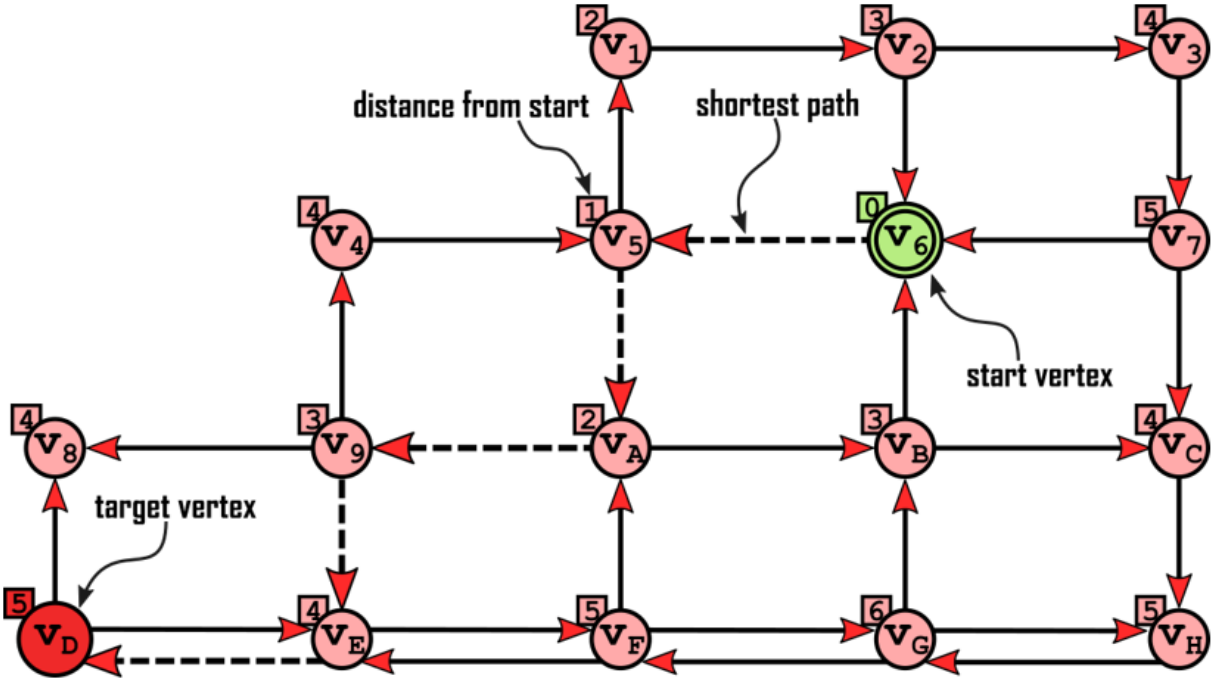

Figure 14.14 The shortest path to destination, and shortest distances, to all the vertices, computed using BFS on the graph in figure 14.9. The shortest path is shown with dashed arrows, while distances are shown next to each vertex.
