4.3.4 How nodecc terminates a virtual machine

To terminate a virtual machine, you first have to select it. To list the virtual machines, use lib/listVMs.js again. After you select the VM, lib/terminateVM.js takes care of termination, as shown in the following code snippet.

Listing 4.7 Terminating an EC2 instance: /lib/terminateVM.js

```
module.exports = (instanceId, cb) => {
  ec2.terminateInstances({              ①
    InstanceIds: [instanceId]           ②
  }, cb);
};
```

① API call to list EC2 instances

② Passes the selected instance ID

That's nodecc: a text UI program for controlling temporary EC2 instances. Take some time to think about what you could create by using your favorite language and the AWS SDK. Chances are high that you might come up with a new business idea!

Cleaning up

Make sure you terminate all started virtual machines before you go on! You learned to use nodecc to terminate instances in the previous section.

The hard parts about using the SDK follow:

- The SDK (or, better, Node.js) follows an imperative approach. You provide all instructions, step by step, in the right order, to get the job done.
