

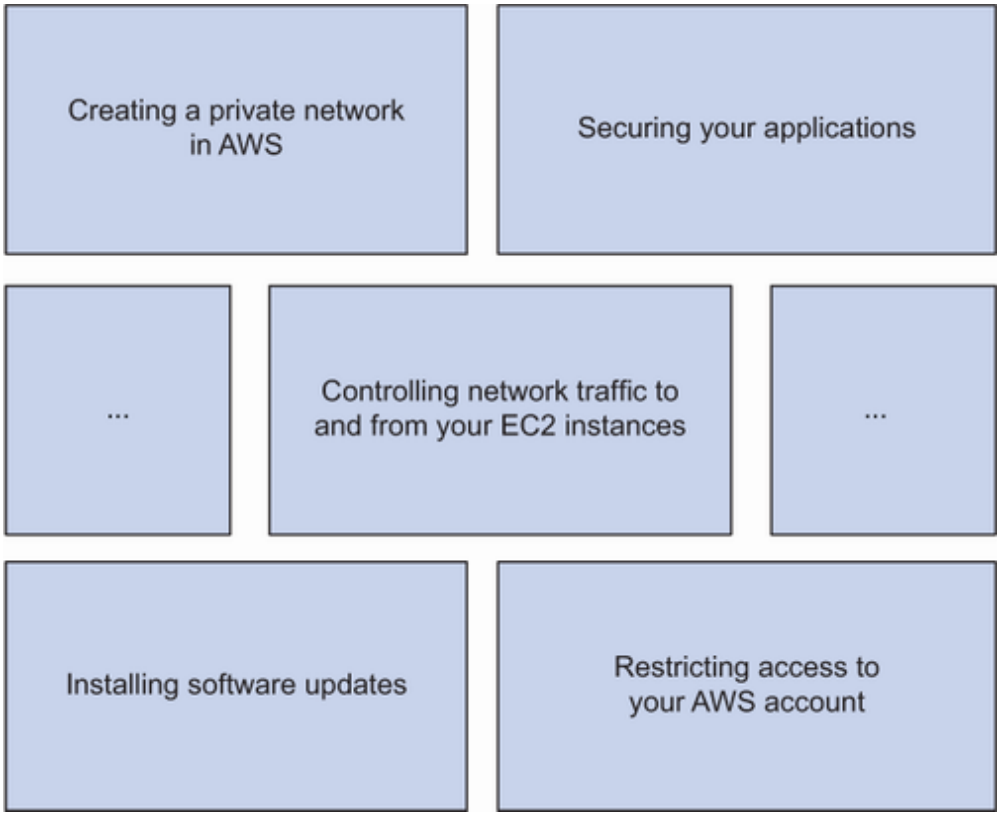

Figure 5.1 To achieve the security of your cloud infrastructure and application, all security building blocks have to be in place.

One important brick is missing: securing your applications. We do not cover application security in our book. When buying or developing applications, you should follow security standards. For example, you need to check user input and allow only the necessary characters, don't save passwords in plain text, and use TLS/SSL to encrypt traffic between your virtual machines and your users.

This is going to be a long chapter—security is such an important topic, there's a lot to cover. But don't worry, we'll take it step by step.

Not all examples are covered by Free Tier
