```
      - !Ref MountTargetSecurityGroup                    ⑥
      SubnetId: !Ref SubnetA                             ⑦
```

① This security group needs no rules. It's just used to mark outgoing traffic from EC2 instances.

② This security group is linked to the mount target.

③ Allows traffic on port 2049

④ Only allows traffic from the security group linked to the EC2 instances

⑤ Attaches the mount target to the filesystem

⑥ Assigns the security group

⑦ Links the mount target with subnet A

Copy the `MountTargetA` resource and also create a mount target for `SubnetB` as shown in listing 9.3.

Listing 9.3 CloudFormation snippet of an EFS mount target and security groups

```
Resources:
  [...]
  MountTargetB:
    Type: 'AWS::EFS::MountTarget'
    Properties:
      FileSystemId: !Ref FileSystem
      SecurityGroups:
      - !Ref MountTargetSecurityGroup
      SubnetId: !Ref SubnetB          ①
```

① Attaches the mount target to subnet B

Next, you will finally mount the /home directory on an EC2 instance.
