

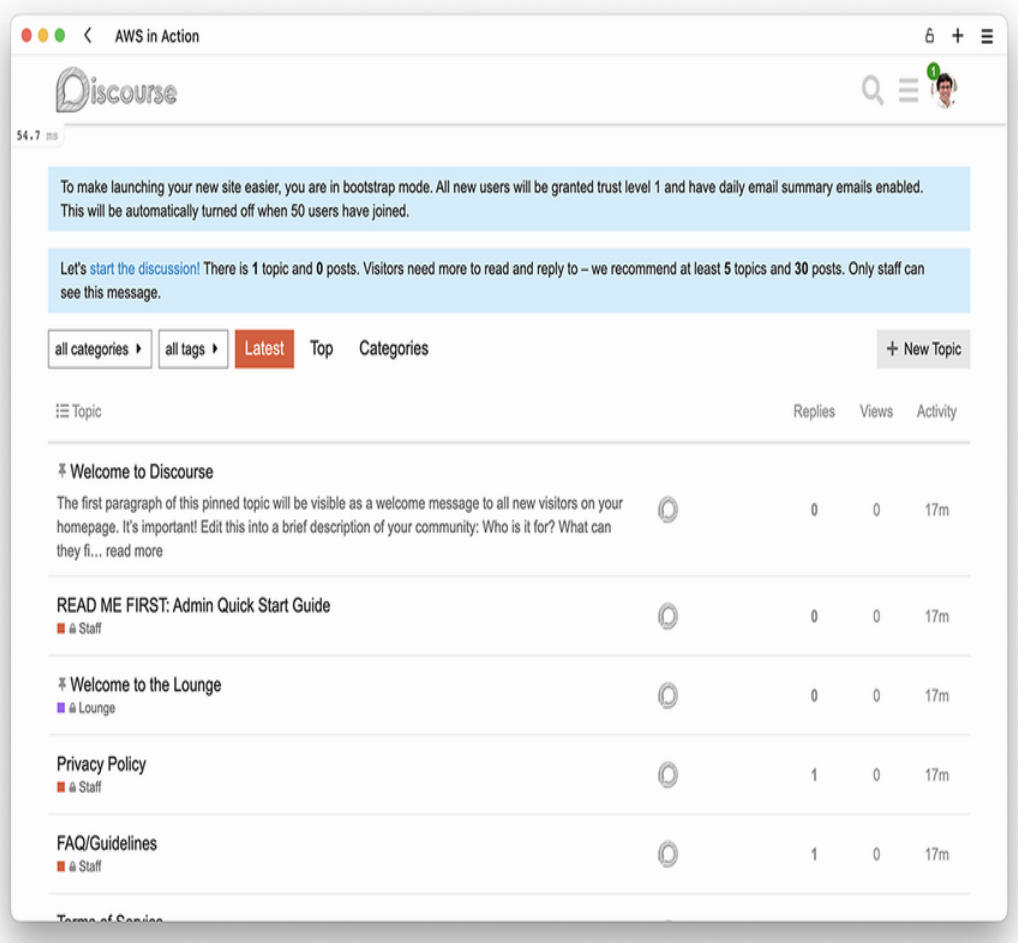

Figure 11.8 Discourse: A platform for community discussion

Discourse requires PostgreSQL as its main data store and uses Redis to cache data and process transient data. In this section, you'll create a CloudFormation template with all the components necessary to run Discourse. Finally, you'll create a CloudFormation stack based on the template to test your work. The necessary components follow:

- *VPC*—Network configuration
- *Cache*—Security group, subnet group, cache cluster
- *Database*—Security group, subnet group, database instance
- *Virtual machine*—Security group, EC2 instance

You'll start with the first component and extend the template in the rest of this section.
