available. So, from an AWS user's perspective, you know only about regions and AZs.

The AZs are connected through low-latency links, so requests between different availability zones aren't as expensive as requests across the internet in terms of latency. The latency within an availability zone (such as from an EC2 instance to another EC2 instance in the same subnet) is lower compared to latency across AZs. The number of availability zones depends on the region. All regions come with three or more availability zones. Keep in mind that AWS charges $0.01/GB for network traffic between availability zones. Figure 13.3 illustrates the concept of availability zones within a region.
