The purpose of AWS CodeDeploy is to automate deployments on EC2, Fargate, and Lambda. Even on-premises machines are supported. The fully managed deployment service is free for EC2, Fargate, and Lambda and costs $0.02 per on-premises machine update. Figure 15.2 shows how CodeDeploy works for EC2 instances, as described here:

1. An engineer uploads a zip archive, including deployment instructions and the binaries or source code.
2. An engineer creates a deployment by choosing the revision and target instances.
3. An agent running on the EC2 instances pulls deployment tasks from CodeDeploy.
4. The agent downloads the zip archive from an S3 bucket.
5. The agent executes the instructions specified in the deployment artifact and copies the binaries or source code.
6. The agent sends a status update to CodeDeploy.
