answer is *decoupling*: put a load balancer or message queue between your EC2 instances and the client. Read on to learn how this works.

16.1.2 Redundancy requires decoupling

In chapter 14, you learned how to use Elastic Load Balancing (ELB) and the Simple Queue Service (SQS) to decouple different parts of a system. You will apply both approaches to build a fault-tolerant system next.

First, figure 16.3 shows how EC2 instances can be made fault tolerant by using redundancy and synchronous decoupling. If one of the EC2 instances crashes, the load balancer stops routing requests to the crashed instances. Then, the Auto Scaling group replaces the crashed EC2 instance within minutes, and the load balancer begins to route requests to the new instance.
