To implement the web server, you'll again use Node.js and the Express web application framework. You'll use the Express framework, but don't feel intimidated because you won't need to understand it in depth to follow along.

Setting up the web server project

As always, you need some boilerplate code to load dependencies, initial AWS endpoints, and things like that. The next listing explains the code to do so.

Listing 16.1 Initializing the Imagery server (server/server.js)

```
const express = require('express');                          ①
const bodyParser = require('body-parser');
const AWS = require('aws-sdk');
const { v4: uuidv4 }  = require('uuid');
const multiparty = require('multiparty');

const db = new AWS.DynamoDB({});                             ②
const sqs = new AWS.SQS({});                                 ③
const s3 = new AWS.S3({});                                   ④

const app = express();                                       ⑤
app.use(bodyParser.json());                                  ⑥

// [...]

app.listen(process.env.PORT || 8080, function() {            ⑦
  console.log('Server started. Open http://localhost:'
➥ + (process.env.PORT || 8080) + ' with browser.');
});
```

① Loads the Node.js modules (dependencies)

② Creates a DynamoDB endpoint

③ Creates an SQS endpoint

④ Creates an S3 endpoint

⑤ Creates an Express application
