```
    'TableName': 'imagery-image'
  }).promise();
}
```

① Fetches the original image from S3

② Writes the original image to a temporary folder on disk

③ Reads the file with the image manipulation library

④ Applies the sepia filter and writes the processed image to disk

⑤ Deletes the original image from the temporary folder

⑥ Reads the processed image

⑦ Uploads the processed image to S3

⑧ Deletes the processed file from the temporary folder

⑨ Updates the database item by calling the updateItem operation

⑩ Updates the state, version, and processed S3 key

Updates only when an item exists, the version equals the expected version, and the state is one of those allowed

The worker is ready to manipulate your images. The next step is to deploy all that code to AWS in a fault-tolerant way.

16.3.4 Deploying the application

As before, you'll use CloudFormation to deploy the application. The infrastructure consists of the following building blocks:

- An S3 bucket for raw and processed images
- A DynamoDB table, `imagery-image`
- An SQS queue and dead-letter queue
- An Application Load Balancer (ALB)
- Two Auto Scaling groups to manage EC2 instances running the server and worker
- IAM roles for the server and worker instances
