1. Open the CloudWatch service, and click Alarms at left.
2. When the load test starts, the alarm called `url2png-`**`HighQueueAlarm-*`** will reach the `ALARM` state after a few minutes.
3. Open the EC2 service, and list all EC2 instances. Watch for an additional instance to launch. At the end, you'll see three instances total (two workers and the EC2 instance running the load test).
4. Go back to the CloudWatch service, and wait until the alarm named `url2png -` **`LowQueueAlarm`**`-*` reaches the `ALARM` state.
5. Open the EC2 service, and list all EC2 instances. Watch for the additional instance to disappear. At the end, you'll see two instances total (one worker and the EC2 instance running the load test).

The entire process will take about 20 minutes.

You've just watched autoscaling in action. The URL2PNG application can now adapt to the current workload, and the problem with slowly generated screenshots has been solved.

Cleaning up

Execute the following commands to delete all resources corresponding to the URL2PNG example:

```
$ URL2PNG_BUCKET=aws cloudformation describe-stacks --stack-name url2png \
➥ --query "Stacks[0].Outputs[?OutputKey=='BucketName'].OutputValue" \
➥ --output text

$ aws s3 rm s3://${URL2PNG_BUCKET} --recursive

$ aws cloudformation delete-stack --stack-name url2png
```

Whenever distributing an application among multiple EC2 instances, you should use an Auto Scaling group. Doing so allows you to spin up identical instances with ease. You get the most out of the possibilities of the cloud when scaling the number of instances based on a schedule or a metric depending on the load pattern.
