- Razor syntax can be used to add dynamic content to pages.
- Razor syntax enables embedding C# code into HTML.
- Razor runtime compilation makes changes to Razor files visible by refreshing the browser.
- Layout pages act as master templates for the whole site.
- Razor Pages applications are console applications with a `Main` method as an entry point. The `Main` method is hidden from view as part of the top-level statements feature in C# 10.
- The `WebApplicationBuilder` is used to configure the application's services and request pipeline.
- The request pipeline determines the behavior of the application.
- The request pipeline is composed of middleware components.
- Middleware is implemented as a `RequestDelegate`—a function that takes an `HttpContext` as a parameter and returns a `Task`.
- Middleware is added to the pipeline via the `WebApplication` object. Middleware can terminate the pipeline or pass control on to the next middleware.
- Middleware is invoked in the order it is registered.
- Simple middleware can be added using inline lambda expressions.
- Complex middleware can be created as a separate class and registered using extension methods on the `IApplicationBuilder` type.
- Middleware classes should use conventions or implement the `IMiddleware` interface.
- Convention-based middleware is instantiated as a singleton and should take dependencies via the `Invoke/InvokeAsync` method.
