logic for calculating the time of day should not be in the Razor page. It should be in the `PageModel` class, which can be tested in isolation, or if the algorithm is likely to be used in multiple places, it should be placed in its own class. You will move the algorithm to the `PageModel` class later in the chapter.

Razor also supports another type of code block: a functions block. A *functions block* is created by adding a `functions` directive followed by opening and closing curly braces:

```
@functions{
    ... C# code goes here
}
```

Again, the code within the functions block is pure C#. You can refactor the algorithm that calculates the part of the day to the functions block as a method as follows.

Listing 3.3 Declaring a method in a functions block

```
@functions{
    string GetPartOfDay(DateTime dt)
    {
        var partOfDay = "morning";
        if (dt.Hour > 12)
        {
            partOfDay = "afternoon";
        }
        if (dt.Hour > 18)
        {
            partOfDay = "evening";
        }
        return partOfDay;
   }
}
<p>It is @GetPartOfDay(DateTime.Now)</p>
```

You could also add this method to a standard code block. The difference between a standard code block and a functions block is that the functions block supports the declaration of public members, whereas they are not supported within a standard code block. However, it is generally advisable to minimize the use of functions blocks for the same reason that you should minimize code blocks altogether. They
