tag helpers in more detail later in this chapter. View components are covered in chapter 14.

COMMENTS IN RAZOR

Razor page files support standard HTML comments within the markup area of the page and C# comments within code blocks. They also support Razor comments, which begin with `@*` and end with `*@`. Anything between Razor comments is not rendered to the browser, unlike the content within HTML comments. The code in listing 3.14 shows a C# `foreach` statement within HTML comments. When the page is rendered, the Razor code is processed, and the resulting list of items appears as a comment in the source code.

Listing 3.14 HTML comments resulting in the content being rendered

```
<!--<ul>
    @foreach(var city in cities)
    {
        <li>@city.Name</li>
    }
</ul>-->
```

The following listing features the same `foreach` statement within Razor comments. None of the contents are included in the source code.

Listing 3.15 Excluding content within Razor comments from source code

```
@*<ul>
    @foreach(var city in cities)
    {
        <li>@city.Name</li>
    }
</ul>*@
```

That completes your look at the Razor syntax, which demonstrates how to embed server-side code within HTML to form a template for a single page. In the following sections, you will find out how to use layout pages and partials to create code templates that are reused across multiple pages.
