To test out creating a partial view, you can cut the `nav` element from the example layout file in listing 3.16 and paste it into a new Razor file named _NavigationPartial .cshtml, which you should place in the Pages\Shared folder. Now that you have a hole in your layout, you need to reference the partial view. The recommended mechanism for including partial views is the partial tag helper. We will cover tag helpers in more detail shortly, but for now, it is enough to know that the following will render the contents of a partial view in a calling page:

```
<partial name=”_NavigationPartial” />
```

The tag helper must be placed in the location you want to output from the partial view to be rendered. In the default template, it goes under the `header` element within the layout.

Listing 3.22 The partial tag helper used to include the content of a partial view

```
<body>
    <div class="container">
        <header class="card alert-success border-5 p-3 mt-3">Header</header>
        <partial name="_NavigationPartial" />
        <div class="row mt-2">
            <div class="col-3">
                <div class="card alert-warning p-5 border-5">
                    Deal Of The Day Widget 1
                </div>
```

Figure 3.6 provides an illustration of the process where the contents of the partial file (_NavigationPartial.cshtml) are inserted into the calling page at the point where the partial tag helper is placed. In this example, the navigation goes under the header, rather than inside it, as in the default project template (figure 3.6).
