The `OnGet` or `OnGetAsync` method is selected for `GET` requests, and the `OnPost` or `OnPostAsync` method is selected for POST requests.

Listing 3.27 shows the `WelcomeModel` class with a simple string property, `Message`, added to it, along with both `OnGet` and `OnPost` handler methods. Each handler sets the value of the `Message` property to report which handler was executed.

Listing 3.27 Different handler methods assigning different values to the `Message` property

```
public class WelcomeModel : PageModel
{
    public string Message { get; set; }     ❶

    public void OnGet()
    {
        Message = "OnGet executed";         ❷
    }

    public void OnPost()
    {
        Message = "OnPost executed";        ❸
    }
}
```

❶ The public property is added, which will be accessible in the Razor page via the Model property.

❷ If the OnGet handler is executed, the message includes "OnGet".

❸ If the OnPost handler is executed, the message includes "OnPost".

Listing 3.28 shows the Welcome Razor page. The page includes an anchor tag helper and a form with its `method` attribute set to `post`. Clicking the link generated by the anchor tag helper will result in a `GET` request, and submitting the form will result in a `POST` request. The `Message` property value, which is set in the respective handler method, is rendered to the output. Figure 3.10 illustrates the differing output based on which method was used to request the page.
