parameter named `id`, and the `Message` property incorporates the value that is bound to the `id` parameter.

Listing 3.29 Adding a parameter to the `OnGet` handler method

```
public void OnGet(int id)                          ❶
{
    Message = $"OnGet executed with id = {id}";    ❷
}
```

❶ A numeric parameter named id is added to the OnGet method.

❷ The value of the parameter is incorporated into the value assigned to the Message property.

The anchor tag in the Razor page is updated to include an `asp-route-id` attribute with a value of `5`, as shown in listing 3.30. The `asp-route-*` attribute is used to pass data in the URL. By default, the data is passed in the query string, with the name of the query string item taken from the part of the attribute represented by the asterisk.

Listing 3.30 Using the asp-route-* attribute on the anchor tag helper to pass a value

```
<a asp-page="/Welcome" asp-route-id="5">Get</a>
```

There is no query string value when you first run the page, so the handler parameter is set to its default value of `0`. The generated value for the anchor tag's `href` attribute is `/Welcome?id=5`. When you click the link, the message is updated to include the parameter value, as shown in figure 3.11.
