more action result types, based on application logic. For example, you might use the parameter value to look up an entry in a database, and if that entry doesn't exist, you will want to return a `NotFoundResult`. Otherwise, you will return a `PageResult`. In that case, you should specify `IActionResult` as the return type for the handler method.

Listing 3.35 Returing `IActionResult` to represent any `ActionResult` type

```
public IActionResult OnGet(int id)     ❶
{
    var data = database.Find(id);      ❷
    if (data == null)
    {
        return NotFound();             ❸
    }
    else
    {
        return Page();                 ❹
    }
}
```

❶ The method returns an IActionResult.

❷ An attempt to locate data matching the parameter value is made.

❸ The NotFound helper method is used to create a NotFoundActionResult if no matching data is returned from the database.

❹ The page is rendered if data was obtained.

At the beginning of this chapter, I mentioned that the `@page` directive denotes a Razor file representing a navigable page that is intended to be browsed. In the next chapter, we will look at the process known as *routing*, which is responsible for ensuring that URLs are mapped to Razor files that include this directive.

Summary

- Razor is templating syntax that enables you to embed server-side code within HTML markup.
- Razor syntax is placed in Razor files, which have a .cshtml extension.
- C# code blocks are enclosed in `@{ ... }`.
