Figure 4.1 Routing middleware is registered after static file middleware. Endpoint middleware is registered at the end of the pipeline.

Listing 4.1 Calling `UseRouting` before `UseEndpoints`

```
app.UseStaticFiles();       ❶
app.UseRouting();           ❷
app.UseAuthorization();
app.MapRazorPages();        ❸
```

❶ Static files middleware is registered before routing.

❷ EndpointRouting middleware is registered in the UseRouting method.

❸ Endpoint middleware is registered at the end of the pipeline and registers endpoints based on Razor Pages conventions.

The role of `EndpointRouting` middleware is to match incoming URLs to endpoints. In the case of a Razor Pages application, an endpoint is generally a Razor page. If a match is made, information about the matched endpoint is added to the `HttpContext`, which is passed along the pipeline. Figure 4.2 illustrates this process. Once the endpoint has been added to the `HttpContext`, it can be accessed via the `GetEndpoint` method of the `HttpContext`.
