Table 4.3 Ambiguous routes might be generated.

Page	Route template
\Pages\Privacy\Index.cshtml	`"Privacy/Index"`
\Pages\Privacy\Index.cshtml	`"Privacy"`
\Pages\Privacy.cshtml	`"Privacy"`

The last two route templates in table 4.3 are identical. There is no way for the endpoint selection process to distinguish which endpoint (page) should match, so the framework throws an `AmbiguousMatchException` when you attempt to navigate to http://domain.com/privacy. Sometimes this type of file configuration is unavoidable, so you will need to know how to resolve ambiguous routes, which is covered in this chapter.

4.2 Customizing route templates

The route template patterns you have seen so far consist of literal text. They require an exact match between characters in the URL and the route template if endpoint matching is to succeed. It would be rather pointless if the routing system was restricted to generating templates that matched existing file paths exactly. As you would expect from any real-world web application framework, Razor Pages provides plenty of scope to customize the route template generation process.

The principal entry point to route template customization is the `@page` directive in the Razor page itself. The only other thing permitted on the first line of a Razor page file, after the `@page` directive, is a string that is used to customize the route template for the page:

```
@page "route-template"
```
