- Handler
- Page

If you would like to follow along, add a new Razor page to the Pages folder named City. The following line of code shows a parameter named `cityName` being added to the route template for the City page:

```
@page "{cityName}"
```

The resulting route template that gets created for the page will be

```
City/{cityName}
```

Any value passed in to the `name` parameter is added to a `RouteValueDictionary` object (literally a dictionary of route values), which is added to a `RouteData` object. Then, within the page, the value can be retrieved using `RouteData.Values`. Listing 4.2 shows how the product route parameter is defined and how the value of the parameter is retrieved in code within the City page.

Listing 4.2 Adding a route parameter to the page and retrieving its value for display

```
@page "{cityName}"                                    ❶
@model CityBreaks.Pages.CityModel

<h2>@RouteData.Values["cityName"] Details</h2>        ❷
```

❶ The route template is added with a parameter in curly braces named "name".

❷ The value of the name parameter is obtained from RouteData.Values and displayed in the page.

Now if you navigate to /City, the first thing you notice is that you get a 404 Not Found error.
