```
[City.cshtml.cs]
public class CityModel : PageModel
{
    public string CityName { get; set; }
    public int? Rating { get; set; }
    public void OnGet(string cityName, int? rating)
    {
        CityName = cityName;
        Rating = rating;
    }
}

[City.cshtml]
@page "{cityName}/{rating?}"
@model CityBreaks.Pages.CityModel
@{
}
<h3>@Model.CityName Details</h3>
<p>Minimum Rating: @Model.Rating.GetValueOrDefault()</p>
```

Multiple parameters within the same segment are also permitted. Each parameter must be separated by literal text that doesn't feature in the parameter value. Suppose your City page accepts a value representing the desired arrival date instead of a rating value being passed in. Since the hyphen doesn't appear in the date parts, the route template can be constructed like this:

```
"{cityName}/{arrivalYear}-{arrivalMonth}-{arrivalDay}"
```

This will match /City/London/2022-4-18, for example, but not /City/London/2022/ 4/18.

4.2.4 Catchall parameters

So far, the route parameters you have seen are used to match specific segments within the URL. There may be occasions when you don't know how many segments the URL will consist of. For example, you may build a content management system that allows users to construct their own
