There is no limit to the number of additional routes you can define for a particular page using this approach, which takes the name of the page to be mapped and a route template that matches the page. This particular example shows a route template with the literal value `"FindMe"`, but the template applied to the `AddPageRoute` method can include parameters and constraints just like the ones you have been working with so far.

4.2.7 Working with PageRouteModel conventions directly

In the previous section, you declared an additional route template for a page through the `AddPageRoute` method. This method offers a convenient way to add new routing conventions to the application, albeit to one page at a time. But what if you wanted to apply a new routing convention to multiple pages, or even all the pages in the application? The `AddPageRoute` approach doesn't scale very well. You could potentially end up with hundreds of lines of code in your `ConfigureServices` method, and you would have to remember to add a new registration for every new page.

When you use the `AddPageRoute` method, the framework creates a new `PageRouteModelConvention` and adds it to the `PageConventionCollection` represented by the `RazorPagesOptions Conventions` property. The convention is represented by the `IPageRouteModelConvention` interface, which you can work with directly to apply new conventions to multiple pages. To illustrate how this works, imagine that your budding application needs to support displaying content in multiple languages.
