Now you can reach the home page with or without a culture included in the URL. If you wanted to make a culture mandatory, you would have updated the existing template instead:

```
foreach (var selector in model.Selectors)
{
    selector.AttributeRouteModel.Template = AttributeRouteModel.CombineTemplates("
{culture}",
                selector.AttributeRouteModel.Template);
}
```

That completes our exploration into how URLs are mapped to individual Razor pages and how you can use a variety of ways to customize the process when necessary. The next section looks at the tools available for generating URLs based on the application's route information.

4.3 Generating URLs

Anyone with a modicum of HTML knowledge knows you create links in your application just by adding anchor elements to a page with the destination URL applied to the `href` attribute as a hardcoded string, so why has this book devoted a section to the topic of generating URLs? If the URL you want to create links to is external to your site, a plain anchor element and a hardcoded `href` value are exactly what you will use. You could also use hardcoded URLs for internal links too, but as you have just been reading, you can alter how URLs map to pages very easily. If you need to adjust how a specific page or group of pages is found, you need to update the URLs that link to those pages in all the locations within the application. Now, that could present a maintenance headache—and the developers of the Razor Pages framework don't like maintenance headaches, so they provided solutions to this issue.
