Razor Pages includes some tools that generate URLs based on the application's routing configuration. So if you change the routing, the links they generate are automatically updated. The main tools are the anchor tag helper, which we have looked at briefly before, and the `LinkGenerator` service. Those are what we will look at next.

4.3.1 The anchor tag helper

As established in the last chapter, tag helpers are components that automate the generation of HTML. The anchor tag helper is responsible for generating an anchor element that links to pages within the application. The `href` attribute's value is the essential part of the anchor element. The anchor tag helper is responsible for generating this based on the routing configuration for the application. If you change the routing system configuration by adjusting a route template for a page or adding a new convention, the output from the tag helper is automatically adjusted accordingly. You don't need to go through your Razor pages to update links all over the application.

As a reminder, following is the anchor tag helper for the Welcome page you added to the navigation in chapter 2:

```
<a class="nav-link text-dark" asp-area="" asp-page="/Welcome">Welcome</a>
```

This particular anchor tag helper includes two custom attributes, both prefixed with `asp-`. Notice that there is no `href` attribute. You cannot include an `href` attribute in an anchor tag helper. If you try to, your application will throw an `InvalidOperationException` at run time. The custom attributes supported by the anchor tag of most interests to Razor Pages applications are as follows:

- `page`
