- page-handler
- route-*
- all-route-data
- host
- protocol
- area

The page, page-handler, and route-* attributes are the ones you will work with most often. The page attribute is the most important; it takes the name of the page (the path without the extension, rooted in the Pages folder) you want to generate a link to, preceded by a forward slash (e.g., /Welcome). You must pass in a valid page name, including path separators if the page is in a subfolder. So if the page you want to generate a link to is located at \Pages\Admin\Index.cshtml, the value you pass to the page attribute will be /Admin/Index. If the routing system cannot find a matching page, it will generate an href attribute with an empty string. Therefore, if you find that the rendered output of an anchor tag helper unexpectedly takes you to the home page of your application, you should double-check the value you assigned to the page attribute.

Some pages have multiple route templates. Where this is the case, the last template will be used to generate the href value (see figure 4.7). The default convention for files named Index.cshtml is to generate two route templates; the first is Index, and the last is an empty string, as you saw earlier. When you pass /Index or /Admin/Index to the asp-page attribute, the resulting output is href="/" or href="/Admin/". You added a third route template for the Index page earlier—"FindMe"—via the AddPageRoute method in Startup,
