The value of the `target` variable, based on the `"{cityName}/{rating?}"` template from listing 4.4, is `"/City/Berlin/4"`. Any properties within the anonymous type that don't have names matching parameter names will be added to the URL query string.

The next listing demonstrates the use of the `PageLink` method to generate an absolute URL. The output, based on the same route template, is `"https://localhost :5001/City/Berlin/4"`.

Listing 4.10 Generating an absolute URL with the `IUrlHelper`

```
public class IndexModel : PageModel
{
    public void OnGet()
    {
        var target = Url.PageLink("City", values: new { cityName = "Berlin",
        ➥ rating = 4 });
    }
}
```

4.3.3 Generating redirect URLs from ActionResults

At the end of the last chapter, we looked at different `ActionResult` types that can be used as a return type for handler methods and the helper methods for creating instances of the `ActionResult` class. Two of those helper methods generate URLs that are included in the location header as part of the response: `RedirectToPage` and `RedirectToPagePermanent`. Both of these methods are used to instruct the browser to redirect to the generated URL. The `RedirectToPage` method also generates an HTTP 302 status code, which indicates that the location change is temporary. In contrast, the `RedirectToPagePermanent` method generates a 301 HTTP status
