code, indicating that the redirection should be viewed as representing a permanent change. You would typically use the latter method when you want to inform search engines that a resource has been moved to a new URL. The following listing shows how to use the `RedirectToPage` method to generate a `RedirectToPageResult` that sends the user to a specific city page.

Listing 4.11 Generating an absolute URL with the `IUrlHelper`

```
public class IndexModel : PageModel
{
    public RedirectToPageResult OnGet()                                    ❶
    {
        return RedirectToPage("City", new { cityName = "Berlin", rating = 4 });❷
    }
}
```

❶ It is good practice to set the handler return type as specifically as possible—in this case, RedirectToPageResult.

❷ The user will be directed to /City/Berlin/4.

If you want to redirect the user to a page within an `area`, you must pass the name of the `area` as a route parameter:

```
return RedirectToPage("/Account/Login", new { area = "Identity" });
```

4.3.4 Customizing URL generation

At the beginning of this chapter, I stated that URLs should be considered to be part of your web application's UI. On that basis, you need to be able to exercise as much control over their generation as possible. You ideally want your URLs to be readable and memorable. The conventions used to generate URLs might not suit your purposes. For example, it is common to use Pascal casing (where the first letter of each word in a compound word is
