capitalized) for Razor page names. Page routes use the same case as the name of the page by default. If, like me, you prefer lowercase URLs in your application, you can use the `RouteOptions` object to configure this in the `Program` class. It is the same `RouteOptions` object you used to add your custom constraint earlier. It has a Boolean property named `LowercaseUrls`, which, when set to `true`, results in the path part of outbound URLs being generated in lowercase.

Listing 4.12 Configuring outbound URL paths to use lowercase

```
builder.Services.Configure<RouteOptions>(options =>
{
    options.LowercaseUrls = true;                                    ❶
    options.ConstraintMap.Add("city", typeof(CityConstraint));
});
```

❶ Setting lowercase as the default for the path part of generated URLs.

The `RouteOptions` object enables you to apply the same case preference for your query strings through its `LowercaseQueryStrings` property, which is also a Boolean:

```
options.LowercaseQueryStrings = true;
```

Going forward, the application you will build while reading this book will have lowercase URLs set to `true`. You won't apply lowercasing to query string values because that will break security tokens, which you will work with in chapter 9 as part of user management.

Some people prefer their URLs to end with a forward slash (`/`). Technically, there is no benefit to doing so, but if you do choose to implement this pattern, you have to be consistent because search engines see *City/London* and *City/London/* as two different URLs. The `RouteOptions` object
