includes a property named `AppendTrailingSlash`, which will always result in the slash being appended when set to `true`:

```
options.AppendTrailingSlash = true;
```

4.3.5 Using parameter transformers to customize route and parameter value generation

You now have your URLs generated in lowercase, but there are still some aspects of URL generation you might want to customize. Let's say you have a page named CityReview.cshtml. The generated URL for this page will be /cityreview, whereas you might prefer each word in the compound word *CityReview* to be separated with a hyphen: `city-review`. This is known as *kebab case* (think of skewers). You could achieve this by naming the page City-Review.cshtml, which will result in a `PageModel` named `City_ReviewModel`. You could change the name of the `PageModel` class if you don't like the underscore in the name, but you might also be under some global naming constraints that prevent you from including the hyphen in the page name in the first place. Another possible solution is to use the `AddPageRoute` method to apply an additional route template, which will be used for URL generation, but you will need to remember to do that for all other pages that might have compound words in their names. So ideally, you want a global solution that affects all pages in the application. Parameter transformers provide a global solution.

Parameter transformers are classes that implement the `IOutboundParameterTransformer` interface that specifies one method: `TransformOutbound`. The method takes an object as a parameter and returns a string. Despite its name, a parameter transformer can
