be used to transform the generated page route as well as the parameter values, depending on how it is registered with the application. The transformation logic is placed in the `TransformOutbound` method.

The following listing shows a parameter transformer that inserts hyphens prior to the first letter of the second and subsequent words in a Pascal case compound word, so *CityReview* becomes *City-Review*, for example.

Listing 4.13 A parameter transformer that acts on a page route

```
using Microsoft.AspNetCore.Routing;                                    ❶
using System.Text.RegularExpressions;                                  ❷

public class KebabPageRouteParameterTransformer :                      ❸
➥ IOutboundParameterTransformer                                       ❸
{                                                                      ❸
    public string TransformOutbound(object value)                      ❸
    {
        if (value == null)                                             ❹
        {
            return null;
        }
        return Regex.Replace(value.ToString(), "([a-z])([A-Z])", "$1-$2"); ❺
    }
}
```

❶ IOutboundParameterTransformer is in the Microsoft.AspNetCore.Routing namespace.

❷ You are using a regular expression in the method body, so you need to add a using directive for the appropriate namespace.

❸ The class implements the IOutboundParameterTransformer interface and its TransformOutbound method.

❹ A null check is needed, just in case the page name passed in is incorrect.

❺ A simple (if there is such a thing) regular expression to identify locations in a string where an uppercase letter follows a lowercase letter and insert a hyphen where they are found

This particular transformer is designed to work on the route of the page, not the parameter values, so it must be registered as a `PageRouteTransformerConvention`. Registration takes place
