```
public class IndexModel : PageModel
{
    public string[] Cities { get; set; }                          ❶
    public void OnGet()
    {
        Cities = new[] { "London", "Berlin", "Paris", "Rome" };   ❷
    }
}
```

❶ An array of string is declared as a public property on the PageModel.

❷ It is assigned the values of a number of cities.

You will iterate over the array within the Razor page and use the anchor tag helper to render links for each city.

Listing 4.15 Generating a list of links to each city

```
<ul>
@foreach (var city in Model.Cities)
{
    <li><a asp-page="/City" asp-route-cityName="@city">@city</a></li>
}
</ul>
```

Remember, you have `LowercaseUrls` set to `true`, so the generated HTML looks like figure 4.8.

```
<ul>
    <li><a href="/city/london">London</a></li>
    <li><a href="/city/berlin">Berlin</a></li>
    <li><a href="/city/paris">Paris</a></li>
    <li><a href="/city/rome">Rome</a></li>
</ul>
```

Figure 4.8 The links rendered by the anchor tag from the data

This is just what you want, but what happens if you include New York in the collection? Well, the space between the two words is URL encoded to `%20`
