when the anchor tag is rendered (figure 4.9).

```
<ul>
    <li><a href="/city/london">London</a></li>
    <li><a href="/city/berlin">Berlin</a></li>
    <li><a href="/city/paris">Paris</a></li>
    <li><a href="/city/rome">Rome</a></li>
    <li><a href="/city/new%20york">New York</a></li>
</ul>
```

Figure 4.9 Spaces in URLs are encoded to %20 by default.

This isn't such a great look, especially if your links start appearing in search engine results with lots of what can best be described by the average visitor as *gobbledygook* in them. You really want to render these route values using the same kebab case as routes to make them more readable, this time replacing spaces in the parameter values with hyphens. You often see this type of thing when a URL includes content like a blog post headline or the name of a book—take, for example, the URL for this book: www.manning.com/books/**asp-net-core-razor-pages-in-action**. The bold part of the URL is often referred to as a *slug*.

You will now transform the parameter value using another parameter transformer. The code for this is shown in the following listing.

Listing 4.16 Transforming spaces into hyphens within a route parameter value

```
public class SlugParameterTransformer :                    ❶
➥ IOutboundParameterTransformer                           ❶
{                                                          ❶
    public string TransformOutbound(object value)          ❶
    {
        return value?.ToString().Replace(" ", "-");        ❷
    }
}
```
