```
<ul>
    <li><a href="/city/london">London</a></li>
    <li><a href="/city/berlin">Berlin</a></li>
    <li><a href="/city/paris">Paris</a></li>
    <li><a href="/city/rome">Rome</a></li>
    <li><a href="/city/new-york">New York</a></li>
</ul>
```

Figure 4.10 The parameter transformer works on outbound routes.

That ends our exploration of the routing system within Razor Pages. You have learned about the default behavior of mapping URLs to route templates, which are generated from the location of the Razor page within an application. You have also learned how to customize this behavior on an individual page basis and a global basis as well as how to pass data in URLs using route parameters.

You have seen how to use the anchor tag helper to generate URLs for links and use the `IUrlHelper` via the Razor page and the `PageModel`'s `Url` property to generate URLs for potential use for other purposes. Finally, you looked at customizing the generated URLs using `RouteOptions` and parameter transformers. The next chapter focuses on using forms within a Razor Pages application to capture and process data.

Summary

- Routing is the process that maps incoming URLs to endpoints and generates outgoing URLs.
- Routing is added as middleware with the `UseRouting` and `UseEndpoints` methods.
