With respect to forms submitted using the `POST` method, after the form contents have been processed successfully on the server, the user is usually redirected to another URL. This procedure is known as the *post-redirect-get* (PRG) pattern and is useful as a mechanism for preventing the user from refreshing the page containing the form, thereby accidentally resubmitting it, which would result in the processing operation being executed again.

It is particularly important to implement this pattern when processing any form that is designed to add items to the application's data store. The last thing you want is duplicate data or your customer to complain that they only ordered one item, yet two have been charged for! Having said that, you won't implement the PRG pattern during the early examples that follow, while you learn how to access the values from the form submission.
