It also has an implicit conversion to string, so if only one value is expected, you can treat it as a string. If there are multiple values, the first one is returned.

5.1.3 Accessing values from Request.Query

As I mentioned earlier, most forms will use the `POST` method, but there will be occasions when the `GET` method is preferred, especially for features like searching with which you might want to be able to store, share, and reuse the search result URL. In this section, you will make two small modifications to the existing code to retrieve the values submitted in a form using the `GET` method.

The only change required to the code presented in listing 5.1 is of the method attribute on the form to specify `"get"`:

```
<form method="get">
```

The `PageModel` code requires two changes, shown in listing 5.3. The handler method should be changed to `OnGet`, and the references to `Request.Form` should be changed to `Request.Query`.

Listing 5.3 Accessing the submitted values from `Request.Query`

```
public class CreateModel : PageModel
{
    public void OnGet()                                                    ❶
    {
        if (!StringValues.IsNullOrEmpty(Request.Query["cityName"]))        ❷
        {                                                                  ❷
            Message = $"You submitted {Request.Query["cityName"]}";        ❷
        }                                                                  ❷
    }
}
```

❶ The handler method is changed to OnGet.
