- Forms
- Route data
- Query strings
- Request body (useful for accessing data posted as JSON, as you will see in chapter 10)

The binding targets supported in Razor Pages are handler parameters and public `PageModel` properties that have been explicitly opted in to model binding.

You already encountered binding to handler parameters in chapter 3, when we looked at working with named handlers. In the next section, we will look at this process in more detail, and after that, we will explore binding to `PageModel` properties in depth.

5.2.1 Using model binding with handler parameters

In this section, you will alter the `OnPost` handler slightly, so you don't access the `Request` object directly. This time, you will rely on model binding to bind the incoming form value to a handler parameter as the binding target. Alter the existing `OnPost` method, so it takes a string parameter named `cityName` and uses that to build the value of the `Message` property.

Listing 5.5 Adding a parameter to the `OnPost` method

```
public class CreateModel : PageModel
{
    public string Message { get; set; }
    public void OnPost(string cityName)          ❶
    {
        Message = $"You submitted {cityName}";   ❷
```
