5.2.2 Using model binding with public properties

In this section, you will look at public properties on the `PageModel` class as a binding target. This is the recommended way to work with the model binder in Razor Pages when the binding source is form data. This approach is recommended because public properties are accessible within the Razor page, where they work with form control tag helpers and can take part in validating user input. You will look at both of those features in detail soon enough, but for now, you will alter the existing `PageModel` class, so it no longer works with handler parameters. You will add a new property to represent the city name while removing both the existing `Message` property and the `OnPost` handler. The new property will be decorated with an attribute named `BindProperty`, which designates the property as a binding target.

Listing 5.6 Binding to a public property

```
public class CreateModel : PageModel
{
    [BindProperty]
    public string CityName { get; set; }      ❶
}
```

❶ CityName is declared as a public property and has the BindProperty attribute applied to it.

Now that the `Message` property has been removed, you need to work directly with the `CityName` property in the Create page instead. The changes are shown in bold in the following listing.

Listing 5.7 Update the Create page to work with the `CityName` property

```
<div class="col-4">
    <form method="post">
        <div class="mb-3">
            <label for="name">Enter city name</label>
            <input class="form-control" type="text" name="cityName" />
```
