You might also start to wonder about the mapping code in the `OnPost` method that takes the values from one object and assigns them to identically named properties on another object. You might think that looks like it could get quite laborious for objects that have many properties. And you would be absolutely right. The good news is there are at least two solutions to speed up the mapping. The first is a very popular open source library called AutoMapper that does this for you. I won't be covering how to use it in this book, but the documentation at the project's site is very good: https://automapper.org/. The second solution may be one you have already noticed if you are using Visual Studio 2022. The ever-improving AI-assisted IntelliCode feature seems to be able to guess the assignments you want to make and often provides the full line of code as a suggestion; you just need to press Tab twice to accept it (figure 5.8).

Figure 5.8 IntelliCode speeds up simple mapping between objects.

The following example shows the `InputModel` class as a public property of the `PageModel`, but it is also possible to apply complex objects as parameters to the `OnPost` handler:

```
public void OnPost(InputModel model)
```
