Most often, you will use the public property approach because it works best with form tag helpers, which you will learn about in greater detail in the next chapter. One key point to mention now is that when you use tag helpers in conjunction with public `PageModel` properties, you don't need to worry about constructing the value of the `name` attribute on the input element because the tag helper generates it for you.

Binding to complex objects during a `GET` request works with complex objects decorated with the `BindProperty` attribute as long as the `SupportsGet` parameter is set to `true`—just as with simple types. Binding also works directly to complex objects that act as a handler parameter.

Listing 5.12 Complex object as a handler parameter

```
public void OnGet(InputModel input)
{
    if (input.CountryName != null)
    {
        Country = new Country
        {
            CountryName = input.CountryName,
            CountryCode = input.CountryCode
        };
    }
}
```

5.2.4 Binding simple collections

So far you have looked at binding single instances of simple or complex types. The model binder also supports binding to collections. This is useful for cases where you might want to enable the user to make multiple selections, for example, or provide them with a form for entering multiple rows of data.
